

3.3 Infinite potential well and 3.4 Heisenberg uncertainty principle

UST Spring 2010

PHYS 225 Applications of Modern Physics: from the atom to the diode

1

The free electron: $V(x) = 0$

$$\Psi(x,t) = A e^{i(kx - \omega t)}$$

 $\Psi(x,t)$ at some instant t 

The probability density: $|\Psi(x,t)|^2 = A^2$

2

Plane Waves

- $\Psi_1(x,t) = \exp(i(k_1x - \omega_1t))$

- $\Psi_2(x,t) = \exp(i(k_2x - \omega_2t))$

- $\Psi_3(x,t) = \exp(i(k_3x - \omega_3t))$

- $\Psi_4(x,t) = \exp(i(k_4x - \omega_4t))$

- etc...

Superposition principle

- If $\Psi_1(x,t)$ and $\Psi_2(x,t)$ are both solutions to wave equation, so is $\Psi_1(x,t) + \Psi_2(x,t)$.

Plane Waves vs. Wave Packets

Plane Wave: $\Psi(x,t) = A \exp(i(kx - \omega t))$

Wave Packet: $\Psi_n(x,t) = \sum_n A_n \exp(i(k_n x - \omega_n t))$

Which one looks more like a particle?

UST Spring 2010 PHYS 225 Applications of Modern Physics: from the atom to the diode 6

Wave packets

A wave packet is:

- A. a bunch of electrons of different energies all traveling together
- B. a short snippet of a wave produced from a wave with a single wavelength
- C. a wave with a localized region of non-zero probability produced by the superposition of many waves of differing wavelengths
- D. all of the above

Wave packets

A wave packet is:

- A. a bunch of electrons of different energies all traveling together
- B. a short snippet of a wave produced from a wave with a single wavelength
- C. a wave with a localized region of non-zero probability produced by the superposition of many waves of differing wavelengths
- D. all of the above

A wave packet is NOT a bunch of electrons! It is a single electron whose wave function can be expressed as a sum of plane waves.

Heisenberg Uncertainty Principle

- $\Delta x \Delta p_x \geq \hbar/2$
- $\Delta y \Delta p_y \geq \hbar/2$
- $\Delta z \Delta p_z \geq \hbar/2$
- $\Delta E \Delta t \geq \hbar/2$

Heisenberg Uncertainty Principle

For copper, work function = 4.7 eV. What is the probability that the electron will be outside of the well? (if copper is at room temperature)

- A. zero chance
- B. very small chance
- C. small chance
- D. likely

b. $1/40 \text{ eV} \ll 4.7 \text{ eV}$. So very small chance ($e^{-4.7/.02}$) an electron could have enough energy to get out.

What does that say about boundary conditions on $\psi(x)$?

- a. $\psi(x)$ must be same $x < 0$, $0 < x < L$, $x > L$,
- b. $\psi(x < 0) \sim 0$, $\psi(x > 0) \neq 0$
- c. $\psi(x) \sim 0$ except for $0 < x < L$

$$\begin{aligned}
 V(x) &\sim \infty, & x < 0 \\
 V(x) &= 0, & 0 < x < L \\
 V(x) &\sim \infty, & x > L
 \end{aligned}$$

Solving the Schrodinger equation for electron wave in 1 D

$$-\frac{\hbar^2}{2m} \frac{\partial^2 \psi(x)}{\partial x^2} + V(x)\psi(x) = E\psi(x)$$

1. Figure out what $V(x)$ is for situation given.
2. Guess or look up functional form of solution.
3. Check solution.
4. Figure out what boundary conditions must be to make sense physically.
5. Figure out values of constants to meet boundary conditions and normalization

$$\int_{-\infty}^{\infty} |\psi(x)|^2 dx = 1$$

6. Multiply by time dependence $\Phi(t) = \exp(-iEt/\hbar)$ to have full solution.

E quantized by boundary conditions:

$$E = \frac{p^2}{2m} = \frac{n^2 \pi^2 \hbar^2}{2mL^2}$$

Does this L dependence make sense?
